28 November 2010

Summary

- *General definition of function 1879* [14] is key to Frege's *formalisation of logic*.
- *Self-application of functions* was at the heart of *Russell's paradox 1902* [44].
- To *avoid paradox* Russell controled function application via *type theory*.
- Russell [45] *1903* gives the first type theory: the *Ramified Type Theory* (RTT).
- RTT is used in Russell and Whitehead's Principia Mathematica [49] 1910–1912.
- *Simple theory of types* (STT): Ramsey [40] *1926*, Hilbert and Ackermann [26] *1928*.
- Church's *simply typed λ-calculus* $\lambda\!\!\rightarrow$ [11] 1940 = λ-calculus + STT.

- The hierarchies of types (and orders) as found in RTT and STT are *unsatisfactory*.
- The *notion of function adopted in the λ-calculus* is *unsatisfactory* (cf. [29]).
- Hence, birth of *different systems of functions and types*, each with *different functional power*.
- We discuss the evolution of functions and types and their use in logic, language and computation.
- We then concentrate on these notions in mathematical vernaculars (as in Automath) and in logic.
- Frege's functions $\neq$ Principia's functions $\neq$ *λ-calculus* functions (1932).
- Not all functions need to be *fully abstracted* as in the λ-calculus. For some functions, their values are enough.

- *Non-first-class functions* allow us to stay at a lower order (keeping decidability, typability, etc.) without losing the flexibility of the higher-order aspects.

- Furthermore, non-first-class functions allow placing the type systems of modern theorem provers/programming languages like ML, LF and Automath more accurately in the modern formal hierarchy of types.

- Another issue that we touch on is the lessons learned from formalising mathematics in logic (à la Principia) and in proof checkers (à la Automath, or any modern proof checker).

Prehistory of Types (Euclid)

- Euclid's *Elements* (circa 325 B.C.) begins with:

  1. A *point* is that which has no part;
  2. A *line* is breadthless length.

     ⋮

  15. A *circle* is a plane figure contained by one line such that all the straight lines falling upon it from one point among those lying within the figure are equal to one another.

- 1..15 *define* points, lines, and circles which Euclid *distinguished* between.

- Euclid always mentioned to which *class* (points, lines, etc.) an object belonged.

Prehistory of Types (Euclid)

- By distinguishing classes of objects, Euclid prevented *undesired/impossible* situations. E.g., whether two points (instead of two lines) are parallel.
- Intuition implicitly forced Euclid to think about the *type* of the objects.
- As intuition does not support the notion of parallel points, he did not even *try* to undertake such a construction.
- In this manner, types have always been present in mathematics, although they were not noticed explicitly until the late 1800s.
- If you studied geometry, then you have an (implicit) understanding of types.

Prehistory of Types (Paradox Threats)

- From 1800, mathematical systems became less intuitive, for several reasons:
  - Very complex or abstract systems.
  - Formal systems.
  - Something with less intuition than a human using the systems: a *computer* or an *algorithm*.
- These situations are *paradox threats*. An example is Frege's Naive Set Theory.
- Not enough intuition to activate the (implicit) type theory to warn against an impossible situation.

Prehistory of Types (formal systems in 19th century)

In the 19th century, the need for a more *precise* style in mathematics arose, because controversial results had appeared in analysis.

- 1821: Many of these controversies were solved by the work of Cauchy. E.g., he introduced *a precise definition of convergence* in his *Cours d'Analyse* [8].

- 1872: Due to the more *exact definition of real numbers* given by Dedekind [13], the rules for reasoning with real numbers became even more precise.

- 1895-1897: Cantor began formalizing *set theory* [6, 7] and made contributions to *number theory*.

Prehistory of Types (formal systems in 19th century)

- 1889: Peano formalized *arithmetic* [37], but did not treat logic or quantification.

- 1879: Frege was not satisfied with the use of natural language in mathematics:

  > ". . . I found the inadequacy of language to be an obstacle; no matter how unwieldy the expressions I was ready to accept, I was less and less able, as the relations became more and more complex, to attain the precision that my purpose required."
  >
  > (*Begriffsschrift*, Preface)

  Frege therefore presented *Begriffsschrift* [14], the first formalisation of logic giving logical concepts via symbols rather than natural language.

Prehistory of Types (formal systems in 19th century)

> "[Begriffsschrift's] first purpose is to provide us with the most reliable test of the validity of a chain of inferences and to point out every presupposition that tries to sneak in unnoticed, so that its origin can be investigated."
>
> (*Begriffsschrift*, Preface)

- 1892-1903 Frege's *Grundgesetze der Arithmetik* [16, 20], could handle elementary arithmetic, set theory, logic, and quantification.

Prehistory of Types (Begriffsschrift's functions)

The introduction of a *very general definition of function* was the key to the formalisation of logic. Frege defined what we will call the Abstraction Principle.

Abstraction Principle 1.

> *"If in an expression, [. . .] a simple or a compound sign has one or more occurrences and if we regard that sign as replaceable in all or some of these occurrences by something else (but everywhere by the same thing), then we call* the part that remains invariant in the expression *a* function, *and* the replaceable part *the* argument *of the function."*
>
> (*Begriffsschrift*, Section 9)

Prehistory of Types (Begriffsschrift's functions)

- Frege put *no restrictions* on what could play the role of *an argument*.
- An argument could be a *number* (as was the situation in analysis), but also a *proposition*, or a *function*.
- Similarly, the *result of applying* a function to an argument did not necessarily have to be a number.
- Functions of more than one argument were constructed by a method that is very close to the method presented by Schönfinkel [47] in 1924.

Prehistory of Types (Begriffsschrift's functions)

With this definition of function, two of the three possible paradox threats occurred:

1. The generalisation of the concept of function made the system more abstract and *less intuitive*.

2. Frege introduced a *formal* system instead of the informal systems that were used up till then. Type theory, that would be helpful in distinguishing between the different types of arguments that a function might take, was left informal.

So, Frege had to proceed with caution. And so he did, at this stage.

Prehistory of Types (Begriffsschrift's functions)

Frege was aware of some typing rule that does not allow to substitute functions for object variables or objects for function variables:

> "if the [. . .] letter [sign] occurs as a function sign, this circumstance [should] be taken into account."
>
> (*Begriffsschrift*, Section 11)

> " Now just as functions are fundamentally different from objects, so also *functions whose arguments are and must be functions* are fundamentally different from *functions whose arguments are objects and cannot be anything else*. I call the latter *first-level*, the former *second-level*."
>
> (*Function and Concept*, pp. 26–27)

Prehistory of Types (Begriffsschrift's functions)

In *Function and Concept* he was aware of the fact that making a *difference between first-level and second-level objects is essential to prevent paradoxes*:

> "The ontological proof of God's existence suffers from the fallacy of treating existence as a first-level concept."
>
> (*Function and Concept*, p. 27, footnote)

The above discussion on functions and arguments show that *Frege did indeed avoid the paradox in his Begriffsschrift*.

Prehistory of Types (Grundgesetze's functions)

The *Begriffsschrift*, however, was only a prelude to Frege's writings.

- In Grundlagen der Arithmetik [15] he argued that mathematics can be seen as a branch of logic.

- In Grundgesetze der Arithmetik [16, 20] he described the elementary parts of arithmetics within an extension of the logical framework of *Begriffsschrift*.

- Frege approached the *paradox threats for a second time* at the end of Section 2 of his *Grundgesetze*.

- He did not want to *apply a function to itself*, but to its course-of-values.

Prehistory of Types (Grundgesetze's functions)

Frege defined "the function $\Phi(x)$ has the same *course-of-values* as the function $\Psi(x)$" by

> "the functions $\Phi(x)$ and $\Psi(x)$ always have the same value for the same argument."
>
> (*Grundgesetze*, p. 7)

- Note that functions $\Phi(x)$ and $\Psi(x)$ may have equal courses-of-values even if they have different definitions.
- E.g., let $\Phi(x)$ be $x \wedge \neg x$, and $\Psi(x)$ be $x \leftrightarrow \neg x$, for all propositions x.

Prehistory of Types (Grundgesetze's functions)

Frege denoted the course-of-values of a function $\Phi(x)$ by $\grave{\varepsilon}\Phi(\varepsilon)$. The definition of equal courses-of-values could therefore be expressed as

$$\grave{\varepsilon}f(\varepsilon) = \grave{\varepsilon}g(\varepsilon) \longleftrightarrow \forall a[f(a) = g(a)]. \tag{1}$$

In modern terminology, we could say that the functions $\Phi(x)$ and $\Psi(x)$ have the same course-of-values if they have the same *graph*.

Prehistory of Types (Grundgesetze's functions)

- The notation $\grave{\varepsilon}\Phi(\varepsilon)$. may be the origin of Russell's notation $\hat{x}\Phi(x)$ for the class of objects that have the property Φ.

- According to a paper by Rosser [43], the notation $\hat{x}\Phi(x)$ has been at the basis of the current notation $\lambda x.\Phi$.

- Church is supposed to have written $\wedge x\Phi(x)$ for the function $x \mapsto \Phi(x)$, writing the hat in front of the x in order to distinguish this function from the class $\hat{x}\Phi(x)$.

Prehistory of Types (Grundgesetze's functions)

- Frege treated *courses-of-values* as *ordinary objects*.
- As a consequence, *a function that takes objects as arguments could have its own course-of-values as an argument*.
- In modern terminology: a function that takes objects as arguments can have its own graph as an argument.

Prehistory of Types (Grundgesetze's functions)

- All essential information of a function is contained in its graph.
- So intuitively, a system in which a function can be applied to its own graph should have similar possibilities as a system in which a function can be applied to itself.
- Frege *excluded the paradox threats* from his system by *forbidding self-application*,
- but due to his *treatment of courses-of-values* these threats were able to *enter his system through a back door*.

Prehistory of Types (Russell's paradox in *Grundgesetze*)

- In 1902, Russell wrote a letter to Frege [44], informing him that he had *discovered a paradox* in his *Begriffsschrift* (*Begriffsschrift does not suffer from a paradox*).

- Russell gave his well-known argument, defining the propositional function $f(x)$ *by* $\neg x(x)$ (in Russell's words: "to be a predicate that cannot be predicated of itself").

- Russell assumed $f(f)$. Then by definition of f, $\neg f(f)$, *a contradiction*. Therefore: $\neg f(f)$ holds. But then (again by definition of f), $f(f)$ holds. Russell concluded that *both* $f(f)$ *and* $\neg f(f)$ hold, a contradiction.

Prehistory of Types (Russell's paradox in *Grundgesetze*)

- *Only six days later*, Frege answered Russell that *Russell's derivation of the paradox was incorrect* [19]. He explained that the *self-application* $f(f)$ *is not possible in the* Begriffsschrift. $f(x)$ is a function, which requires an *object* as an argument, and a function cannot be an object in the *Begriffsschrift*.

- In the same letter, however, Frege explained that *Russell's argument could be amended to a paradox* in the system of his Grundgesetze, using the *course-of-values* of functions.

- Frege's amendment was shortly explained in that letter, but he added an appendix of eleven pages to the second volume of his *Grundgesetze* in which he provided a very detailed and correct description of the paradox.

Prehistory of Types (Russell's paradox in *Grundgesetze*)

- Let function $f(x)$ be: $\neg\forall\varphi[(\grave{\alpha}\varphi(\alpha) = x) \longrightarrow \varphi(x)]$ and write $K = \grave{\varepsilon}f(\varepsilon)$.
- Which of $f(K)$ or $\neg f(K)$ hold?
- Actually, *both* $f(K)$ and $\neg f(K)$ hold.
- Recall that (1) is: $\grave{\varepsilon}f(\varepsilon) = \grave{\varepsilon}g(\varepsilon) \longleftrightarrow \forall a[f(a) = g(a)]$.
  By (1), for any function $g(x)$: $\grave{\varepsilon}g(\varepsilon) = \grave{\varepsilon}f(\varepsilon) \longrightarrow g(K) = f(K)$. This implies $f(K) \longrightarrow ((\grave{\varepsilon}g(\varepsilon) = K) \longrightarrow g(K))$.
- As this holds for any function $g(x)$, we have:
  $f(K) \longrightarrow \forall\varphi[(\grave{\varepsilon}\varphi(\varepsilon) = K) \rightarrow \varphi(K)]$ (a)

Prehistory of Types (Russell's paradox in *Grundgesetze*)

- On the other hand, for any function g,
  $\forall\varphi[(\grave{\varepsilon}\varphi(\varepsilon) = K) \to \varphi(K)] \longrightarrow ((\grave{\varepsilon}g(\varepsilon) = K) \to g(K))$.

- Substituting $f(x)$ for $g(x)$ results in:
  $\forall\varphi[(\grave{\varepsilon}\varphi(\varepsilon) = K) \to \varphi(K)] \longrightarrow ((\grave{\varepsilon}f(\varepsilon) = K) \to f(K))$

- and as $\grave{\varepsilon}f(\varepsilon) = K$ by definition of K, $\forall\varphi[(\grave{\varepsilon}\varphi(\varepsilon) = K) \to \varphi(K)] \longrightarrow f(K)$.

- Using the definition of f, we obtain
  $\forall\varphi[(\grave{\varepsilon}\varphi(\varepsilon) = K) \to \varphi(K)] \longrightarrow \neg\forall\varphi[(\grave{\varepsilon}\varphi(\varepsilon) = K) \to \varphi(K)]$ (b)

Prehistory of Types (Russell's paradox in *Grundgesetze*)

- by (b) and reductio ad absurdum, $\neg\forall\varphi[(\grave{\alpha}\varphi(\alpha) = K) \rightarrow \varphi(K)]$, or shorthand: $f(K)$ (c)

- Applying (a) results in $\forall\varphi[(\grave{\alpha}\varphi(\alpha) = K) \rightarrow \varphi(K)]$, which implies $\neg\neg\forall\varphi[(\grave{\alpha}\varphi(\alpha) = K) \rightarrow \varphi(K)]$, or shorthand: $\neg f(K)$ (d)

- (c) and (d) *contradict* each other.

Prehistory of Types (How wrong was Frege?)

In the history of the Russell Paradox, Frege is often depicted as the pitiful person whose system was inconsistent. This suggests that Frege's system was the only one that was inconsistent, and that Frege was very inaccurate in his writings. On these points, history does Frege an injustice.

In fact, Frege's system was much more accurate than other systems of those days. Peano's work, for instance, was *less precise* on several points:

- Peano *hardly paid attention to logic* especially quantification theory;
- Peano *did not make a strict distinction* between his *symbolism* and the *objects underlying this symbolism*. Frege was much more accurate on this point (see Frege's paper *Über Sinn und Bedeutung* [17]);

Prehistory of Types (How wrong was Frege?)

- Frege *made a strict distinction* between a *proposition* (as an object) and the assertion *of a proposition*. Frege denoted a *proposition*, by $-A$, and *its assertion* by $\vdash A$. Peano did not make this distinction and simply wrote A.

Nevertheless, Peano's work was very popular, for several reasons:

- Peano had *able collaborators*, and a *better eye for presentation and publicity*.

- Peano bought *his own press* to supervise the printing of his own journals Rivista di Matematica and Formulaire [38]

Prehistory of Types (How wrong was Frege?)

- Peano used a *familiar symbolism* to the notations used in those days.
- Many of *Peano's notations*, like $\in$ for "is an element of", and $\supset$ for logical implication, are used in *Principia Mathematica*, and are actually still in use.
- Frege's work did not have these advantages and was hardly read before 1902
- When Peano published his formalisation of mathematics in 1889 [37] he clearly did not know Frege's *Begriffsschrift* as he did not mention the work, and was not aware of Frege's formalisation of quantification theory.

Prehistory of Types (How wrong was Frege?)

- Peano considered quantification theory to be "abstruse" in [38]:

  "In this respect my *[Frege]* conceptual notion of 1879 is superior to the Peano one. Already, at that time, I specified all the laws necessary for my designation of generality, so that nothing fundamental remains to be examined. These laws are few in number, and I do not know why they should be said to be abstruse. If it is otherwise with the Peano conceptual notation, then this is due to the unsuitable notation."

  ([18], p. 376)

Prehistory of Types (How wrong was Frege?)

- In the last paragraph of [18], Frege concluded:

  ". . . I observe merely that the *Peano notation* is unquestionably *more convenient for the typesetter*, and in many cases *takes up less room* than mine, but that these advantages seem to me, due to the inferior perspicuity and *logical defectiveness*, to have been paid for too dearly — at any rate for the purposes I want to pursue."

  (*Ueber die Begriffschrift des Herrn Peano und meine eigene*, p. 378)

Prehistory of Types (paradox in Peano and Cantor's systems)

- Frege's system was *not the only paradoxical* one.
- The Russell Paradox can be derived in *Peano's system* as well, by defining the class $K \stackrel{\text{def}}{=} \{x \mid x \notin x\}$ and deriving $K \in K \longleftrightarrow K \notin K$.
- In *Cantor's Set Theory* one can derive the paradox via the same class (or *set*, in Cantor's terminology).

Prehistory of Types (paradoxes)

- Paradoxes were already widely known in *antiquity*.
- The oldest logical paradox: the *Liar's Paradox* "This sentence is not true", also known as the Paradox of Epimenides. It is referred to in the Bible (Titus 1:12) and is based on the confusion between language and meta-language.
- The *Burali-Forti paradox* ([5], 1897) is the first of the modern paradoxes. It is a paradox within Cantor's theory on ordinal numbers.
- *Cantor's paradox* on the largest cardinal number occurs in the same field. It discovered by Cantor around 1895, but was not published before 1932.

Prehistory of Types (paradoxes)

- Logicians considered these paradoxes to be *out of the scope of logic*:
  The *Liar's Paradox* can be regarded as a problem of *linguistics*.
  The *paradoxes of Cantor and Burali-Forti* occurred in what was considered in those days a *highly questionable* part of mathematics: Cantor's Set Theory.

- The Russell Paradox, however, was *a paradox that could be formulated in all* the systems that were presented at the end of the 19th century (except for Frege's *Begriffsschrift*). It was at the very basics of logic. It could not be disregarded, and a solution to it had to be found.

- In 1903-1908, Russell suggested the use of *types* to solve the problem [46].

Prehistory of Types (vicious circle principle)

When Russell proved Frege's *Grundgesetze* to be inconsistent, Frege was not the only person in *trouble*. In Russell's letter to Frege (1902), we read:

"I am on the point of finishing a book on the principles of mathematics"

(*Letter to Frege*, [44])

Russell *had to find a solution* to the paradoxes, before finishing his book.

His paper Mathematical logic as based on the theory of types [46] *(1908)*, in which a first step is made towards the Ramified Theory of Types, started with a description of the most important contradictions that were known up till then, including Russell's own paradox. He then concluded:

Prehistory of Types (vicious circle principle)

> "In all the above contradictions there is a common characteristic, which we may describe as *self-reference* or *reflexiveness*. [...] In each contradiction something is said about all cases of some kind, and from what is said a new case seems to be *generated*, which both *is and is not* of the same kind as the cases of which *all* were concerned in what was said."
>
> (*Ibid.*)

Russell's plan was, *to avoid the paradoxes* by *avoiding all possible self-references*. He postulated the *"vicious circle principle"*:

Ramified Type Theory

"*Whatever involves all of a collection must not be one of the collection.*"

(Mathematical logic as based on the theory of types)

- Russell applies this principle *very strictly*.
- He implemented it using *types*, in particular the so-called ramified *types*.
- The type theory of 1908 was elaborated in Chapter II of the Introduction to the famous *Principia Mathematica* [49] (1910-1912).

Ramified Type Theory and Principia

- In the *Principia*, *mathematics was founded on logic*, as far as possible.
- A very *formal and accurate* build-up of mathematics, avoiding the logical paradoxes.
- The *logical part* of the *Principia* was *based* on the works of *Frege*. This was acknowledged by Whitehead and Russell in the preface, and can also be seen throughout the description of Type Theory.
- The notion of *function is based on Frege's Abstraction Principles*.

Ramified Type Theory and Principia

- The *Principia notation* $\hat{x}\,f(x)$ for a class looks very *similar to Frege's* $\grave{\varepsilon}\,f(\varepsilon)$ for course-of-values.
- An important difference is that Whitehead and Russell treated functions as first-class citizens. Frege used courses-of-values when speaking about functions.
- In the *Principia* a direct approach was possible.
- The description of the Ramified Theory of Types (RTT) in the *Principia* was, though extensive, *still informal*.

Ramified Type Theory and Principia

- Type Theory had *not yet* become an *independent subject*. The theory

  "only recommended itself to us in the first instance by its ability to solve certain contradictions. ..... it has also a certain consonance with common sense which makes it inherently credible"

  (*Principia Mathematica*, p. 37)

- Type Theory was not introduced because it was interesting on its own, but because it had to serve as a *tool* for logic and mathematics.

- A *formalisation* of Type Theory, therefore, was *not considered* in those days.

Ramified Type Theory and Principia

- Though the *description* of the ramified type theory in the *Principia* was still informal, it was *clearly present* throughout the work.
- Types in the *Principia* have a double hierarchy: *(simple) types* and *orders*.
- It was *not mentioned very often*, but when necessary, Russell made a remark on the ramified type theory.

Ramified Type Theory and Principia

- There is *no definition of "type"* in the *Principia*, only a definition of *"being of the same type"*:

  "*Definition of* being of the same type. The following is a step-by-step definition, the definition for higher types presupposing that for lower types. We say that u and v *are of the same type* if

  1. both are individuals,
  2. both are elementary [propositional] functions (in Principia, they only take elementary propositions as value) taking arguments of the same type,
  3. u is a pf and v is its negation,
  4. u is $\varphi\hat{x}$ *$\varphi\hat{x}$ is a pf that has x as a free variable* or $\psi\hat{x}$, and v is $\varphi\hat{x} \vee \psi\hat{x}$, where $\varphi\hat{x}$ and $\psi\hat{x}$ are elementary pfs,
  5. u is $(y).\varphi(\hat{x}, y)$ *forall* and v is $(z).\psi(\hat{x}, z)$, where $\varphi(\hat{x}, \hat{y})$, $\psi(\hat{x}, \hat{y})$ are of the same type,

6. both are elementary propositions,
7. u is a proposition and v is $\sim u$ *negation* or
8. u is $(x).\varphi x$ and v is $(y).\psi y$, where $\varphi\hat{x}$ and $\psi\hat{x}$ are of the same type."

(*Principia Mathematica*, $*9{\cdot}131$, p. 133)

- There are some omissions in Russell and Whitehead's definition.

Ramsey's Simple Types

- The ideas behind simple types was already explained by Frege (see earlier quotes from *Function and Concept*).

- *Ramsey's Simple types*:

  1. 0 is a simple type, the type of *individuals*.
  2. If $t_1, \ldots, t_n$ are simple types, then also $(t_1, \ldots, t_n)$ is a simple type.[1]
     $n = 0$ is allowed: then we obtain the simple type $()$ of *propositions*.
  3. All simple types can be constructed using the rules 1 and 2.

[1] $(t_1, \ldots, t_n)$ is the type of pfs that should take n arguments, the ith argument having type t_i.

Ramsey's Simple Types

- The propositional function $\mathtt{R(x)}$ should have type (0), as it takes one individual as argument.
- The proposition $S(a)$ has type $()$.
- We conclude that in $\mathtt{z(R(x), S(a))}$, we must substitute pfs of type $((0), ())$ for z. Therefore, $\mathtt{z(R(x), S(a))}$ has type $(((0), ()))$.

Whitehead and Russell's Ramified Types

- With *simple types*, the type of a pf only depends on the *types of the arguments* that it can take.
- In the *Principia*, a *second hierarchy* is introduced by regarding also *the types of the variables that are bound by a quantifier* (see *Principia*, pp. 51–55).
- Whitehead and Russell consider, for instance, the propositions $\mathtt{R(a)}$ and $\forall \mathtt{z}{:}()[\mathtt{z}() \vee \neg \mathtt{z}()]$ to be of a *different level*.
- The first is an *atomic proposition*, while the latter is based on the pf $\mathtt{z}() \vee \neg \mathtt{z}()$.

Whitehead and Russell's Ramified Types

- The pf $\mathsf{z}() \vee \neg \mathsf{z}()$ involves an arbitrary proposition z, therefore $\forall \mathsf{z}{:}()[\mathsf{z}() \vee \neg \mathsf{z}()]$ *quantifies over all* propositions z.
- According to the *vicious circle principle*, $\forall \mathsf{z}{:}()[\mathsf{z}() \vee \neg \mathsf{z}()]$ cannot belong to this collection of propositions.
- This problem is solved by dividing types into *orders* which are natural numbers.
- *Basic* propositions are of order 0. In $\forall \mathsf{z}{:}()[\mathsf{z}() \vee \neg \mathsf{z}()]$ we must mention the *order of the propositions over which is quantified*. The pf $\forall \mathsf{z}{:}()^{n}[\mathsf{z}() \vee \neg \mathsf{z}()]$ quantifies over *all propositions of order* n, and has order $n + 1$.

Whitehead and Russell's Ramified Types

1. 0^0 is a ramified type of order 0;

2. If $t_1^{a_1}, \ldots, t_n^{a_n}$ are ramified types, and $a \in \mathbb{N}$, $a > \max(a_1, \ldots, a_n)$, then $(t_1^{a_1}, \ldots, t_n^{a_n})^a$ is a ramified type of order a (if $n = 0$ then take $a \geq 0$);

3. All ramified types can be constructed using the rules 1 and 2.

0^0; $(0^0)^1$; $\left((0^0)^1, (0^0)^4\right)^5$; and $\left(0^0, ()^2, \left(0^0, (0^0)^1\right)^2\right)^7$ are *all ramified types*.

$\left(0^0, \left(0^0, (0^0)^2\right)^2\right)^7$ is *not a ramified type*.

Predicative Types

- In the type $(0^0)^1$, all *orders are "minimal"*, i.e., not higher than strictly necessary. Unlike $(0^0)^2$ where orders are not minimal.

- Types in which all orders are minimal are called predicative and play a special role in the Ramified Theory of Types.

  1. 0^0 is a predicative type;
  2. If ${t_1}^{a_1}, \ldots, {t_n}^{a_n}$ are predicative types, and $a = 1 + \max(a_1, \ldots, a_n)$ (take $a = 0$ if $n = 0$), then $(t_1^{a_1}, \ldots, t_n^{a_n})^a$ is a predicative type;
  3. All predicative types can be constructed using the rules 1 and 2 above.

Problems of Ramified Type Theory

- The main part of the *Principia* is devoted to the development of logic and mathematics using the legal pfs of the ramified type theory.

- *ramification*/division of simple types into orders make RTT not easy to use.

- **(Equality)** $\mathtt{x} =_{\mathrm{L}} \mathtt{y} \overset{\mathrm{def}}{\leftrightarrow} \forall \mathtt{z}[\mathtt{z}(\mathtt{x}) \leftrightarrow \mathtt{z}(\mathtt{y})]$.
  In order to express this general notion in RTT, we have to incorporate *all* pfs $\forall \mathtt{z} : (0^0)^n[\mathtt{z}(\mathtt{x}) \leftrightarrow \mathtt{z}(\mathtt{y})]$ for $n > 1$, and this cannot be expressed in one pf.

- Not possible to give a constructive proof of the theorem of the least upper bound within a ramified type theory.

Axiom of Reducibility

- It is not possible in RTT to give a definition of an object that refers to the class to which this object belongs (because of the Vicious Circle Principle). Such a definition is called an *impredicative definition*.

- An object defined by an impredicative definition is of a higher order than the order of the elements of the class to which this object should belong. This means that the defined object has an *impredicative type*.

- But impredicativity is not allowed by the vicious circle principle.

- Russell and Whitehead tried to solve these problems with the so-called axiom of reducibility.

Axiom of Reducibility

- *(Axiom of Reducibility)* For each formula f, there is a formula g with a *predicative* type such that f and g are (logically) equivalent.

- The validity of the Axiom of Reducibility has been questioned from the moment it was introduced.

- In the 2nd edition of the *Principia*, Whitehead and Russell admit:

  "This axiom has a purely pragmatic justification: it leads to the desired results, and to no others. But clearly it is not the sort of axiom with which we can rest content."

  (*Principia Mathematica*, p. xiv)

Axiom of Reducibility

- Though Weyl [48] made an effort to develop analysis within the Ramified Theory of Types (without the Axiom of Reducibility),

- and various parts of mathematics can be developed within RTT and without the Axiom,

- the general attitude towards RTT (without the axiom) was that the system was too restrictive, and that a *better solution* had to be found.

Deramification

- Ramsey considers it essential to divide the paradoxes into two parts:

- One group of paradoxes is removed

  > "by pointing out that a propositional function cannot significantly take itself as argument, and by dividing functions and classes into a hierarchy of types according to their possible arguments."
  >
  > (The Foundations of Mathematics, p. 356)

  This means that a class can never be a member of itself. The paradoxes solved by introducing the hierarchy of types (but not orders), like the Russell paradox, and the Burali-Forti paradox, are logical or syntactical paradoxes;

Deramification

- The second group of paradoxes is excluded by the hierarchy of orders. These paradoxes (like the Liar's paradox, and the Richard Paradox) are based on the confusion of language and meta-language. These paradoxes are, therefore, not of a purely mathematical or logical nature. When a proper distinction between object language and meta-language is made, these so-called semantical paradoxes disappear immediately.

- Ramsey agrees with the part of the theory that eliminates the syntactic paradoxes. I.e., RTT without the orders of the types.

- The second part, the hierarchy of orders, does not gain Ramsey's support.

Deramification

- By accepting the hierarchy in its full extent one either has to accept the Axiom of Reducibility or reject ordinary real analysis.
- Ramsey is supported in his view by Hilbert and Ackermann [26].
- They all suggest a deramification of the theory, i.e. leaving out the orders of the types.
- When making a proper distinction between language and meta-language, the deramification will not lead to a re-introduction of the (semantic) paradoxes.

Deramification

- *Deramification* and the *Axiom of Reducibility* are both *violations of the Vicious Circle Principle*. Gödel [23] fills the gap why they can be *harmlessly made*

> "it seems that the vicious circle principle [. . .] *applies* only if the entities involved are *constructed by ourselves*. In this case there must clearly exist a *definition* (namely the description of the construction) which does *not refer to a totality* to which the object defined belongs, because the construction of a thing can certainly not be based on a totality of things to which the thing to be constructed itself belongs. If, however, it is a question of objects that *exist independently of our constructions*, there is *nothing in the least absurd in the existence of totalities* containing members, which can be described only by reference to this totality."
>
> (Russell's mathematical logic)

Deramification

- This turns the Vicious Circle Principle into a *philosophical principle* that will be easily *accepted by intuitionists* but that will be *rejected*, at least in its full strength, by mathematicians with a more *platonic* point of view.

- Gödel is supported in his ideas by *Quine* [39], sections 34 and 35.

- Quine's *criticism on impredicative* definitions (for instance, the definition of the least upper bound of a nonempty subset of the real numbers with an upper bound) is *not on the definition* of a special symbol, but rather on the very assumption of the existence of such an object at all.

Deramification

- Quine states that even for *Poincaré*, who was an *opponent of impredicative definitions and deramification*, one of the doctrines of *classes is that they are there "from the beginning"*. So, even for Poincaré *there should be no evident fallacy in impredicative definitions*.

- The *deramification* has played an *important role* in the development of *type theory*. In *1932 and 1933*, Church presented his (untyped) *λ-calculus* [9, 10]. *In 1940* he combined this theory with a deramified version of Russell's theory of types to the system that is known as the simply typed λ-calculus

The Simple Theory of Types

- Ramsey [40], and Hilbert and Ackermann [26], *simplified* the Ramified Theory of Types RTT by removing the orders. The result is known as the Simple Theory of Types *(*STT*)*.

- Nowadays, STT is known via Church's formalisation in λ-calculus. However, STT *already existed (1926) before λ-calculus did (1932)*, and is therefore not inextricably bound up with λ-calculus.

- How to obtain STT from RTT? Just *leave out all the orders* and the references to orders (including the notions of predicative and impredicative types).

Church's Simply Typed λ-calculus $\lambda\!\rightarrow$

- The *types* of $\lambda\!\rightarrow$ are defined as follows:
  - ι *individuals* and o *propositions* are types;
  - If α and β are types, then so is $\alpha \rightarrow \beta$.
- The *terms* of $\lambda\!\rightarrow$ are the following:
  - $\neg$, $\wedge$, $\forall_\alpha$ for each type α, and $\imath_\alpha$ for each type α, are terms;
  - A *variable* is a term;
  - If A, B are terms, then so is AB;
  - If A is a term, and x a variable, then $\lambda x{:}\alpha.A$ is a term.
- *(β)* $\quad (\lambda x{:}\alpha.A)B \rightarrow_\beta A[x := B]$.

Typing rules in Church's Simply Typed λ-calculus $\lambda\!\rightarrow$

- $\Gamma \vdash \neg : o \rightarrow o$;

  $\Gamma \vdash \wedge : o \rightarrow o \rightarrow o$;

  $\Gamma \vdash \forall_\alpha : (\alpha \rightarrow o) \rightarrow o$;

  $\Gamma \vdash \imath_\alpha : (\alpha \rightarrow o) \rightarrow \alpha$;

- $\Gamma \vdash x : \alpha$ if $x{:}\alpha \in \Gamma$;

- If $\Gamma, x{:}\alpha \vdash A : \beta$ then $\Gamma \vdash (\lambda x{:}\alpha.A) : \alpha \rightarrow \beta$;

- If $\Gamma \vdash A : \alpha \rightarrow \beta$ and $\Gamma \vdash B : \alpha$ then $\Gamma \vdash (AB) : \beta$.

Comparing $\lambda\!\!\rightarrow$ with STT and RTT

- Apart from the orders, RTT *is a subsystem of* $\lambda\!\!\rightarrow$.

- The rules of RTT, and the method of deriving the types of pfs have a *bottom-up character*: one can only introduce a variable of a certain type in a context Γ, if there is a pf that has that type in Γ. In $\lambda\!\!\rightarrow$, one can introduce variables of any type without wondering whether such a type is inhabited or not.

- Church's $\lambda\!\!\rightarrow$ is more general than RTT in the sense that Church does not only describe (typable) *propositional* functions. In $\lambda\!\!\rightarrow$, also functions of type $\tau \rightarrow \iota$ (where ι is the type of individuals) can be described, and functions that take such functions as arguments, etc..

Limitation of the simply typed λ-calculus

- $\lambda\!\!\rightarrow$ is very restrictive.
- Numbers, booleans, the identity function have to be defined at every level.
- We can represent (and type) terms like $\lambda x : o.x$ and $\lambda x : \iota.x$.
- We cannot type $\lambda x : \alpha.x$, where α can be instantiated to any type.
- This led to new (modern) type theories that allow more general notions of functions (e.g, *polymorphic*).

The evolution of functions with Frege, Russell and Church

- Historically, functions have long been treated as a kind of meta-objects.
- Function *values* were the important part, not abstract functions.
- In the *low level/operational approach* there are only function values.
- The sine-function, is always expressed with a value: $\sin(\pi)$, $\sin(x)$ and properties like: $\sin(2x) = 2\sin(x)\cos(x)$.
- In many mathematics courses, one calls $f(x)$—and not f—the function.
- Frege, Russell and Church wrote $x \mapsto x+3$ resp. as $x+3$, $\hat{x}+3$ and $\lambda x.x+3$.
- Principia's *functions are based on Frege's Abstraction Principles* but can be first-class citizens. Frege used courses-of-values to speak about functions.
- Church made every function a first-class citizen. This is rigid and does not represent the development of logic in 20th century.

- In *Principia Mathematica* [49]: If, for some a, there is a proposition ϕa, then there is a function $\phi\hat{x}$, and vice versa.
- The function ϕ is not a separate entity but always has an argument.

Functionalisation and Instantiation

[32] assessed evolution of the function concept from two points of vue:

- *Functionalisation*: the construction of a function out of an expression, as in constructing the function $\lambda_x.x \times 3 + x$ from the expression $2 \times 3 + 2$.

- Functionalisation is
  - *Abstraction from a subexpression* e.g., moving from $2 \times 3 + 2$ to $x \times 3 + x$
  - *Function construction* e.g., turning $x \times 3 + x$ into $\lambda_x.x \times 3 + x$.

- *Instantiation*: the calculation of a function value when a suitable argument is assigned to the function, as in the construction of $2 \times 3 + 2$ by applying the function $\lambda_x.x \times 3 + x$ to 2.

- Instantiation is:
  - *Application construction* e.g., $(\lambda_x.x \times 3 + x)2$ the application of $\lambda_x.x \times 3 + x$ to 2
  - *Concretisation to a subexpression* e.g., calculating $(\lambda_x.x \times 3 + x)2$ to $2 \times 3 + 2$.

Functionalisation and Instantiation for Frege, Russell and Church

- Frege [14] focuses on abstraction from a subexpression and does not employ function construction. He does not distinguish the function $x \times 3 + x$ from the expression $x \times 3 + x$ and uses the notation $\grave{x}(x \times 3 + x)$ for what he calls the *course-of-value* of the function.

- Principia allows both parts of functionalisation and writes $\hat{x} \times 3 + \hat{x}$ for the function (see $*9{\cdot}14$ and $*9{\cdot}15$ of [49]).

- The λ-calculus focuses on function construction and does not employ abstraction from a subexpression. This means that we have to go all the way to obtain $\lambda_x.x \times 3 + x$. The abstraction from $2 \times 3 + 2$ to $x \times 3 + x$ is not included in the syntax.

λ-calculus does not fully represent functionalisation

1. Abstraction from a subexpression $2 + 3 \mapsto x + 3$
2. Function construction $x + 3 \mapsto \lambda x.x + 3$
3. Application construction $(\lambda x.x + 3)2$
4. Concretisation to a subexpression $(\lambda x.(x + 3))2 \rightarrow 2 + 3$

- cannot abstract only half way: $x + 3$ is not a function, $\lambda x.x + 3$ is.
- cannot apply $x + 3$ to an argument: $(x + 3)2$ does not evaluate to 2+3.

Common features of modern types and functions

- We can *construct* a type by abstraction. (Write $A : *$ for A *is a type*)
  - $\lambda_{y:A}.y$, the identity over A *has type* $A \to A$
  - $\lambda_{A:*}.\lambda_{y:A}.y$, the polymorphic identity *has type* $\Pi_{A:*}.A \to A$
- We can *instantiate* types. E.g., if $A = \mathbb{N}$, then the identity over $\mathbb{N}$
  - $(\lambda_{y:A}.y)[A := \mathbb{N}]$ *has type* $(A \to A)[A := \mathbb{N}]$ or $\mathbb{N} \to \mathbb{N}$.
  - $(\lambda_{A:*}.\lambda_{y:A}.y)\mathbb{N}$ *has type* $(\Pi_{A:*}.A \to A)\mathbb{N} = (A \to A)[A := \mathbb{N}]$ or $\mathbb{N} \to \mathbb{N}$.
- $(\lambda x{:}\alpha.A)B \to_\beta A[x := B]$ $\qquad$ $(\Pi x{:}\alpha.A)B \to_\Pi A[x := B]$
- Write $A \to A$ as $\Pi_{y:A}.A$ when y not free in A.

The Barendregt Cube

- Syntax: $A ::= x \mid * \mid \Box \mid AB \mid \lambda x{:}A.B \mid \Pi x{:}A.B$
- Formation rule: $$\frac{\Gamma \vdash A : s_1 \quad \Gamma, x{:}A \vdash B : s_2}{\Gamma \vdash \Pi x{:}A.B : s_2} \quad \text{if } (s_1, s_2) \in \boldsymbol{R}$$

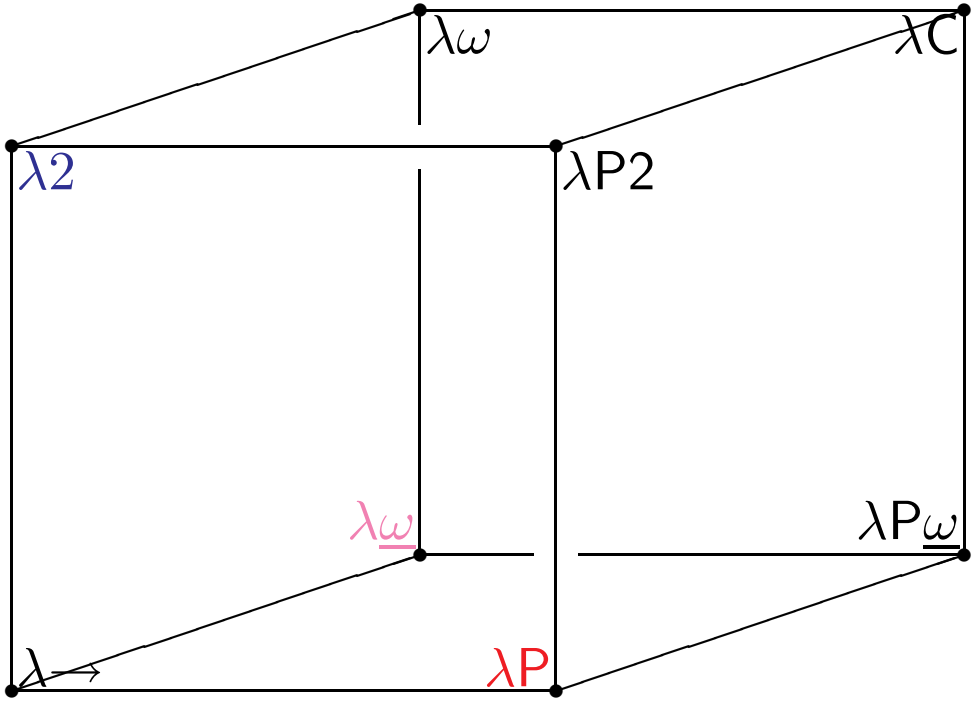
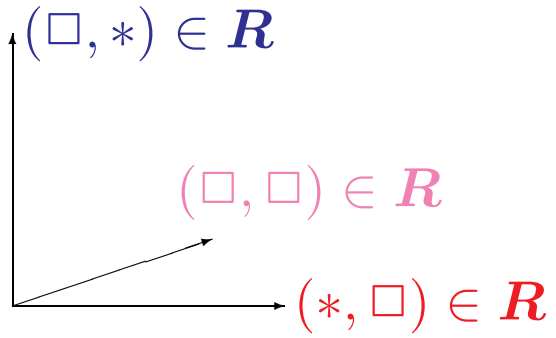
The Barendregt Cube





Typing Polymorphic identity needs $(\Box, *)$

- $$\frac{y : * \vdash y : * \qquad y : *, x{:}y \vdash y : *}{y : * \vdash \Pi x{:}y.y : *}$$ by (Π) $(*, *)$

- $$\frac{y : *, x : y \vdash x : y \qquad y : * \vdash \Pi x{:}y.y : *}{y : * \vdash \lambda x : y.x : \Pi x{:}y.y}$$ by (λ)

- $$\frac{\vdash * : \Box \qquad y : * \vdash \Pi x{:}y.y : *}{\vdash \Pi y : *.\Pi x{:}y.y : *}$$ by (Π) $(\Box, *)$

- $$\frac{y : * \vdash \lambda x : y.x : \Pi x{:}y.y \qquad \vdash \Pi y : *.\Pi x{:}y.y : *}{\vdash \lambda y : *.\lambda x : y.x : \Pi y : *.\Pi x{:}y.y}$$ by (λ)

The story so far of the evolution of functions and types

- Functions have gone through a long process of evolution involving various degrees of abstraction/construction/instantiation/concretisation/evaluation.
- Types too have gone through a long process of evolution involving various degrees of abstraction/construction/instantiation/concretisation/evaluation.
- During their progress, some aspects have been added or removed.
- In this talk we argue that their progresses have been interlinked and that their abstraction/construction/instantiation/concretisation/evaluation have much in common.
- We also argue that some of the aspects that have been dismissed during their evolution need to be re-incorporated.

From the point of vue of ML

- When Robin Milner designed the language ML, he wanted to to use all of system F (the second order polymorphic λ-calculus).
- He could not do so because it was not known then whether type checking and type finding are decidable.
- So, Milner used a fragment of system F for which it was known that type checking and type finding are decidable.
- Just as well since 23 years later Wells showed that type checking and type finding in system F are undecidable.
- This meant that ML has polymorphism but not all the polymorphic power of system F.
- The question is, what system of functions an types does ML use?

- A clean answer can be given when we re-incorporate the low-level function notion used by Frege and Russell and dismissed by Church.

- ML treats let val id $=$ (fn $x \Rightarrow x$) in (id id) end as this Cube term
  $(\lambda \mathsf{id}{:}(\Pi\alpha{:}*.\ \alpha \to \alpha).\ \mathsf{id}(\beta \to \beta)(\mathsf{id}\,\beta))(\lambda\alpha{:}*.\ \lambda x{:}\alpha.\ x)$

- To type this in the Cube, the $(\Box, *)$ rule is needed (i.e., $\lambda 2$).

- ML's typing rules forbid this expression:
  let val id $=$ (fn $x \Rightarrow x$) in (fn $y \Rightarrow y\,y$)(id id) end
  Its equivalent Cube term is this well-formed typable term of $\lambda 2$:
  $(\lambda \mathsf{id} : (\Pi\alpha{:}*.\ \alpha \to \alpha).$
  $\quad(\lambda y{:}(\Pi\alpha{:}*.\ \alpha \to \alpha).\ y(\beta \to \beta)(y\,\beta))$
  $\quad(\lambda\alpha{:}*.\ \mathsf{id}(\alpha \to \alpha)(\mathsf{id}\,\alpha)))$
  $(\lambda\alpha{:}*.\ \lambda x{:}\alpha.\ x)$

- Therefore, ML should not have the full Π-formation rule $(\Box, *)$.

- ML has limited access to the rule $(\Box, *)$.

- ML's type system is none of those of the eight systems of the Cube.
- [28] places the type system of ML on our refined Cube (between $\lambda 2$ and $\lambda\underline{\omega}$).

LF

- LF [24] is often described as λP of the Barendregt Cube.
- Use of Π-formation rule $(*, \Box)$ is very restricted in the practical use of LF [21].
- The only need for a type $\Pi x{:}A.B : \Box$ is when the Propositions-As-Types principle PAT is applied during the construction of the type $\Pi\alpha{:}\mathtt{prop}.*$ of the operator Prf where for a proposition Σ, Prf(Σ) is the type of proofs of Σ.

$$\frac{\mathtt{prop}{:}* \vdash \mathtt{prop}{:}* \qquad \mathtt{prop}{:}*, \alpha{:}\mathtt{prop} \vdash *{:}\Box}{\mathtt{prop}{:}* \vdash \Pi\alpha{:}\mathtt{prop}.* : \Box}.$$

- In LF, this is the only point where the Π-formation rule $(*, \Box)$ is used.
- But, Prf is only used when applied $\Sigma{:}\mathtt{prop}$. We never use Prf on its own.
- This use is in fact based on a parametric constant rather than on Π-formation.

- Hence, the practical use of LF would not be restricted if we present Prf in a parametric form, and use $(*, \Box)$ as a parameter instead of a Π-formation rule.

- [28] finds a more precise position of LF on the Cube (between $\lambda\!\!\rightarrow$ and λP).

Parameters: What and Why

- We speak about *functions with parameters* when referring to functions with variable values in the *low-level* approach. The x in $f(x)$ is a parameter.

- Parameters enable the same expressive power as the high-level case, while allowing us to stay at a lower order. E.g. first-order with parameters versus second-order without [33].

- Desirable properties of the lower order theory (decidability, easiness of calculations, typability) can be maintained, without losing the flexibility of the higher-order aspects.

- This low-level approach is still worthwhile for many exact disciplines. In fact, both in logic and in computer science it has certainly not been wiped out, and for good reasons.

Automath

- The first tool for mechanical representation and verification of mathematical proofs, AUTOMATH, has a parameter mechanism.

- Mathematical text in AUTOMATH written as a finite list of *lines* of the form:

  $x_1 : A_1, \ldots, x_n : A_n \vdash g(x_1, \ldots, x_n) = t : T.$

  Here g is a new name, an abbreviation for the expression t of type T and $x_1, \ldots, x_n$ are the parameters of g, with respective types $A_1, \ldots, A_n$.

- Each line introduces a new definition which is inherently parametrised by the variables occurring in the context needed for it.

- Developments of ordinary mathematical theory in AUTOMATH [3] revealed that this combined definition and parameter mechanism is vital for keeping proofs manageable and sufficiently readable for humans.

Extending the Cube with parametric constants, see [28]

- We add parametric constants of the form $c(b_1, \ldots, b_n)$ with $b_1, \ldots, b_n$ terms of certain types and $c \in \mathcal{C}$.
- $b_1, \ldots, b_n$ are called the *parameters* of $c(b_1, \ldots, b_n)$.
- $\mathfrak{S}$ allows several kinds of Π-constructs. We also use a set $\boldsymbol{P}$ of (s_1, s_2) where $s_1, s_2 \in \{*, \Box\}$ to allow several kinds of parametric constants.
- $(s_1, s_2) \in \boldsymbol{P}$ means that we allow parametric constants $c(b_1, \ldots, b_n) : A$ where $b_1, \ldots, b_n$ have types $B_1, \ldots, B_n$ of sort s_1, and A is of type s_2.
- If both $(*, s_2) \in \boldsymbol{P}$ and $(\Box, s_2) \in \boldsymbol{P}$ then combinations of parameters allowed. For example, it is allowed that B_1 has type $*$, whilst B_2 has type $\Box$.

The Cube with parametric constants

- Let $(*,*) \subseteq \mathfrak{S}, \boldsymbol{P} \subseteq \{(*,*),(*,\Box),(\Box,*),(\Box,\Box)\}$.

- $\lambda\mathfrak{S}\boldsymbol{P} = \lambda\mathfrak{S}$ and the two rules **($\vec{\mathbf{C}}$-weak)** and **($\vec{\mathbf{C}}$-app)**:

$$\frac{\Gamma \vdash b : B \quad \Gamma, \Delta_i \vdash B_i : s_i \quad \Gamma, \Delta \vdash A : s}{\Gamma, c(\Delta) : A \vdash b : B} \; (s_i, s) \in \boldsymbol{P}, c \text{ is } \Gamma\text{-fresh}$$

$$\frac{\begin{array}{lcll} \Gamma_1, c(\Delta){:}A, \Gamma_2 & \vdash & b_i{:}B_i[x_j{:=}b_j]_{j=1}^{i-1} & (i = 1, \ldots, n) \\ \Gamma_1, c(\Delta){:}A, \Gamma_2 & \vdash & A : s & (\text{if } n = 0) \end{array}}{\Gamma_1, c(\Delta){:}A, \Gamma_2 \vdash c(b_1, \ldots, b_n) : A[x_j{:=}b_j]_{j=1}^{n}}$$

$\Delta \equiv x_1{:}B_1, \ldots, x_n{:}B_n.$
$\Delta_i \equiv x_1{:}B_1, \ldots, x_{i-1}{:}B_{i-1}$

Properties of the Refined Cube

- (Correctness of types) If $\Gamma \vdash A : B$ then ($B \equiv \Box$ or $\Gamma \vdash B : S$ for some sort S).
- (Subject Reduction SR) If $\Gamma \vdash A : B$ and $A \twoheadrightarrow_\beta A'$ then $\Gamma \vdash A' : B$
- (Strong Normalisation) For all $\vdash$-legal terms M, we have $\mathsf{SN}_{\twoheadrightarrow_\beta}(M)$.
- Other properties such as Uniqueness of types and typability of subterms hold.
- $\lambda\mathfrak{S}\boldsymbol{P}$ is the system which has Π-formation rules $\boldsymbol{R}$ and parameter rules $\boldsymbol{P}$.
- Let $\lambda\mathfrak{S}\boldsymbol{P}$ parametrically conservative (i.e., $(s_1, s_2) \in \boldsymbol{P}$ implies $(s_1, s_2) \in \boldsymbol{R}$).
  - The parameter-free system $\lambda\mathfrak{S}$ is at least as powerful as $\lambda\mathfrak{S}\boldsymbol{P}$.
  - If $\Gamma \vdash_{\mathfrak{S}\boldsymbol{P}} a : A$ then $\{\Gamma\} \vdash_{\boldsymbol{R}} \{a\} : \{A\}$.

Example

- $\boldsymbol{R} = \{(*,*),(*,\Box)\}$

  $\boldsymbol{P}_1 = \emptyset \qquad \boldsymbol{P}_2 = \{(*,*)\} \qquad \boldsymbol{P}_3 = \{(*,\Box)\} \qquad \boldsymbol{P}_4 = \{(*,*),(*,\Box)\}$

  All $\lambda\boldsymbol{R}\boldsymbol{P}_i$ for $1 \leq i \leq 4$ with the above specifications are all equal in power.

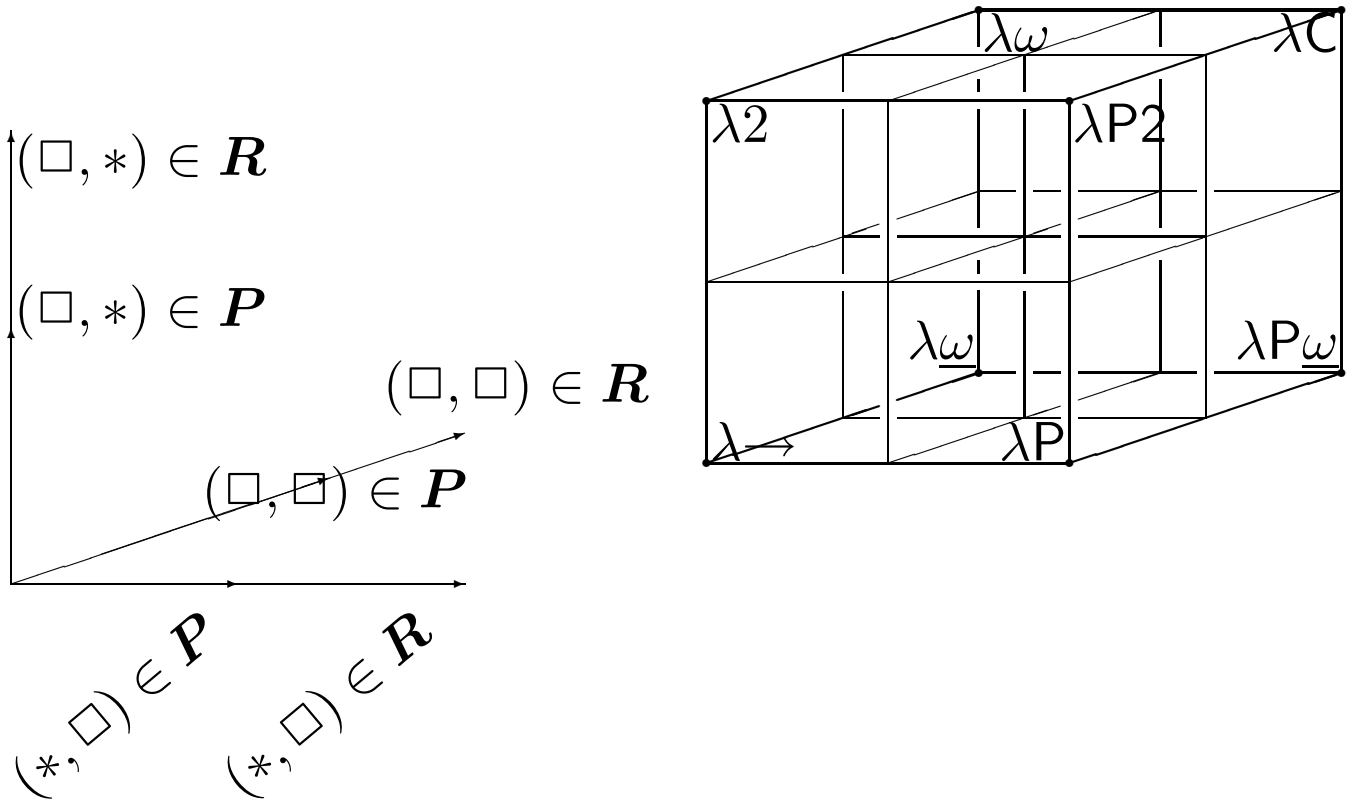
- $\boldsymbol{R}_5 = \{(*,*)\} \qquad \boldsymbol{P}_5 = \{(*,*),(*,\Box)\}.$

  $\lambda{\rightarrow} \;<\; \lambda\boldsymbol{R}_5\boldsymbol{P}_5 \;<\; \lambda$P: we can to talk about predicates:

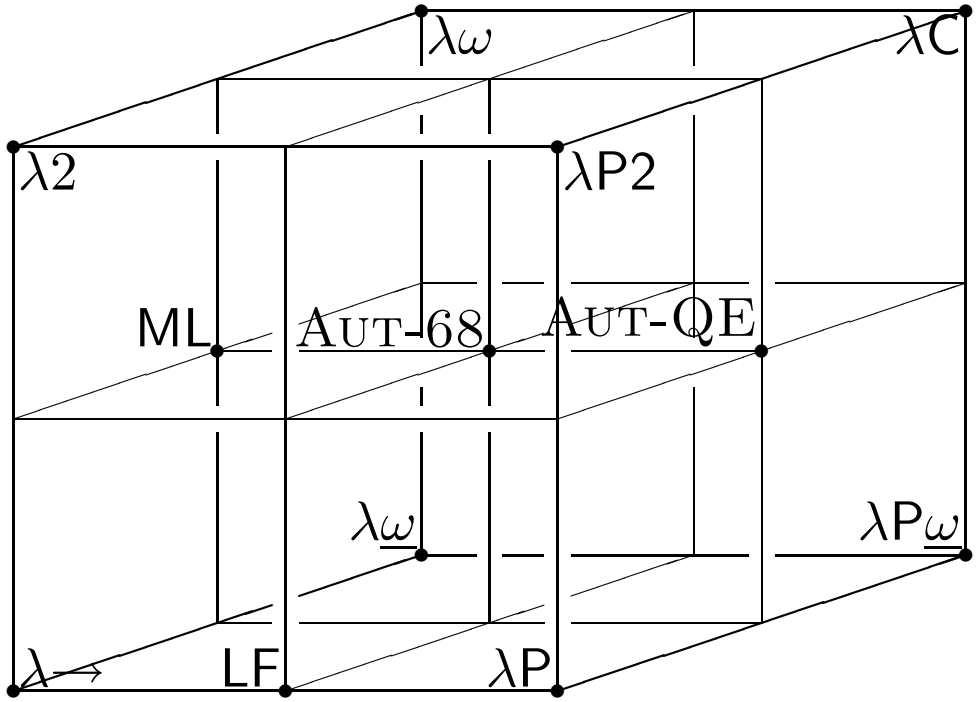
$$\begin{array}{rcl}
\alpha & : & *, \\
\mathtt{eq}(\mathtt{x}{:}\alpha, \mathtt{y}{:}\alpha) & : & *, \\
\mathtt{refl}(\mathtt{x}{:}\alpha) & : & \mathtt{eq}(\mathtt{x},\mathtt{x}), \ . \\
\mathtt{symm}(\mathtt{x}{:}\alpha, \mathtt{y}{:}\alpha, \mathtt{p}{:}\mathtt{eq}(\mathtt{x},\mathtt{y})) & : & \mathtt{eq}(\mathtt{y},\mathtt{x}), \\
\mathtt{trans}(\mathtt{x}{:}\alpha, \mathtt{y}{:}\alpha, \mathtt{z}{:}\alpha, \mathtt{p}{:}\mathtt{eq}(\mathtt{x},\mathtt{y}), \mathtt{q}{:}\mathtt{eq}(\mathtt{y},\mathtt{z})) & : & \mathtt{eq}(\mathtt{x},\mathtt{z})
\end{array}$$

  eq not possible in $\lambda{\rightarrow}$.

The refined Barendregt Cube



LF, ML, AUT-68, and AUT-QE in the refined Cube



Logicians versus mathematicians and induction over numbers

- Logician uses `ind: Ind` as proof term for an application of the induction axiom. The type `Ind` can only be described in $\lambda\boldsymbol{R}$ where $\boldsymbol{R} = \{(*,*),(*,\Box),(\Box,*)\}$:

$$\texttt{Ind} = \Pi p{:}(\mathbb{N}\to *).p0\to(\Pi n{:}\mathbb{N}.\Pi m{:}\mathbb{N}.pn\to Snm\to pm)\to\Pi n{:}\mathbb{N}.pn \quad (2)$$

- Mathematician uses `ind` only with $P : \mathbb{N}\to *$, $Q : P0$ and $R : (\Pi n{:}\mathbb{N}.\Pi m{:}\mathbb{N}.Pn\to Snm\to Pm)$ to form a term $(\texttt{ind}PQR){:}(\Pi n{:}\mathbb{N}.Pn)$.

- The use of the induction axiom by the mathematician is better described by the parametric scheme (p, q and r are the *parameters* of the scheme):

$$\texttt{ind}(p{:}\mathbb{N}\to *, q{:}p0, r{:}(\Pi n{:}\mathbb{N}.\Pi m{:}\mathbb{N}.pn\to Snm\to pm)) : \Pi n{:}\mathbb{N}.pn \quad (3)$$

- The logician's type `Ind` is not needed by the mathematician and the types that occur in 3 can all be constructed in $\lambda\boldsymbol{R}$ with $\boldsymbol{R} = \{(*,*)(*,\Box)\}$.

Logicians versus mathematicians and induction over numbers

- Mathematician: only *applies* the induction axiom and doesn't need to know the proof-theoretical backgrounds.

- A logician develops the induction axiom (or studies its properties).

- $(\Box, *)$ is not needed by the mathematician. It is needed in logician's approach in order to form the Π-abstraction $\Pi p{:}(\mathbb{N} \to *).\cdots)$.

- Consequently, the type system that is used to describe the mathematician's use of the induction axiom can be weaker than the one for the logician.

- Nevertheless, the parameter mechanism gives the mathematician limited (but for his purposes sufficient) access to the induction scheme.

- Parameters enable the same expressive power as the high-level case, while allowing us to stay at a lower order. E.g. first-order with parameters versus second-order without [33].

- Desirable properties of the lower order theory (decidability, easiness of calculations, typability) can be maintained, without losing the flexibility of the higher-order aspects.

- Parameters enable us to find an exact position of type systems in the generalised framework of type systems.

- Parameters describe the difference between *developers* and *users* of systems.

Identifying λ and Π (see [30])

- In the cube of the generalised framework of type systems, we saw that the syntax for terms (functions) and types was intermixed with the only distinction being λ- versus Π-abstraction.

- We unify the two abstractions into one.
  $\mathcal{T}_\flat ::= \mathcal{V} \mid \boldsymbol{S} \mid \mathcal{T}_\flat \mathcal{T}_\flat \mid \flat \mathcal{V}{:}\mathcal{T}_\flat.\mathcal{T}_\flat$

- $\mathcal{V}$ is a set of variables and $\boldsymbol{S} = \{*, \Box\}$.

- The β-reduction rule becomes $(\flat)$ $\qquad (\flat_{x:A}.B)C \to_\flat B[x := C]$.

- Now we also have the old Π-reduction $(\Pi_{x:A}.B)C \to_\Pi B[x := C]$ which treats type instantiation like function instantiation.

- The type formation rule becomes

$$(\flat_1) \quad \frac{\Gamma \vdash A : s_1 \quad \Gamma, x{:}A \vdash B : s_2}{\Gamma \vdash (\flat x{:}A.B) : s_2} \; (s_1, s_2) \in \boldsymbol{R}$$

(axiom) $$\langle\rangle \vdash * : \Box$$

(start) $$\frac{\Gamma \vdash A : s}{\Gamma, x{:}A \vdash x : A}\ x \notin \mathrm{DOM}(\Gamma)$$

(weak) $$\frac{\Gamma \vdash A : B \quad \Gamma \vdash C : s}{\Gamma, x{:}C \vdash A : B}\ x \notin \mathrm{DOM}(\Gamma)$$

($\flat_2$) $$\frac{\Gamma, x{:}A \vdash b : B \quad \Gamma \vdash (\flat x{:}A.B) : s}{\Gamma \vdash (\flat x{:}A.b) : (\flat x{:}A.B)}$$

(app$\flat$) $$\frac{\Gamma \vdash F : (\flat x{:}A.B) \quad \Gamma \vdash a : A}{\Gamma \vdash Fa : B[x{:=}a]}$$

(conv) $$\frac{\Gamma \vdash A : B \quad \Gamma \vdash B' : s \quad B =_\beta B'}{\Gamma \vdash A : B'}$$

Translations between the systems with 2 binders and those with one binder

- For $A \in \mathcal{T}$, we define $\overline{A} \in \mathcal{T}_\flat$ as follows:
  - $\overline{s} \equiv s \qquad \overline{x} \equiv x \qquad \overline{AB} \equiv \overline{A}\,\overline{B}$
  - $\overline{\lambda_{x:A}.B} \equiv \overline{\Pi_{x:A}.B} \equiv \flat_{x:\overline{A}}.\overline{B}.$
- For contexts we define: $\overline{\langle\rangle} \equiv \langle\rangle \quad \overline{\Gamma, x:A} \equiv \overline{\Gamma}, x:\overline{A}.$
- For $A \in \mathcal{T}_\flat$, we define $[A]$ to be $\{A' \in \mathcal{T}$ such that $\overline{A'} \equiv A\}$.
- For context, obviously: $[\Gamma] \equiv \{\Gamma'$ such that $\overline{\Gamma'} \equiv \Gamma\}$.

Isomorphism of the cube and the $\flat$-cube

- If $\Gamma \vdash A : B$ then $\overline{\Gamma} \vdash_\flat \overline{A} : \overline{B}$.
- If $\Gamma \vdash_\flat A : B$ then there are unique $\Gamma' \in [\Gamma]$, $A' \in [A]$ and $B' \in [B]$ such that $\Gamma' \vdash_\pi A' : B'$.
- The $\flat$-cube enjoys all the properties of the cube except the unicity of types.

Organised multiplicity of Types for $\vdash_\flat$ and $\to_\flat$ [30]

For many type systems, unicity of types is not necessary (e.g. Nuprl).

We have however an organised multiplicity of types.

1. If $\Gamma \vdash_\flat A : B_1$ and $\Gamma \vdash_\flat A : B_2$, then $B_1 \overset{\diamond}{=}_\flat B_2$.

2. If $\Gamma \vdash_\flat A_1 : B_1$ and $\Gamma \vdash_\flat A_2 : B_2$ and $A_1 =_\flat A_2$, then $B_1 \overset{\diamond}{=}_\flat B_2$.

3. If $\Gamma \vdash_\flat B_1 : s_1$, $B_1 =_\flat B_2$ and $\Gamma \vdash_\flat A : B_2$ then $\Gamma \vdash_\flat B_2 : s_1$.

4. Assume $\Gamma \vdash_\flat A : B_1$ and $(\Gamma \vdash_\flat A : B_1)^{-1} = (\Gamma', A', B_1')$. Then $B_1 =_\flat B_2$ if:

   (a) either $\Gamma \vdash_\flat A : B_2$, $(\Gamma \vdash_\flat A : B_2)^{-1} = (\Gamma', A'', B_2')$ and $B_1' =_\beta B_2'$,
   (b) or $\Gamma \vdash_\flat C : B_2$, $(\Gamma \vdash_\flat C : B_2)^{-1} = (\Gamma', C', B_2')$ and $A' =_\beta C'$.

Extending the cube with Π-reduction loses subject reduction [31]

If we change (appl) by (new appl) in the cube we lose subject reduction.

$$\text{(appl)}\quad \frac{\Gamma \vdash F : (\Pi_{x:A}.B) \qquad \Gamma \vdash a : A}{\Gamma \vdash Fa : B[x := a]}$$

$$\text{(new appl)}\quad \frac{\Gamma \vdash F : (\Pi_{x:A}.B) \qquad \Gamma \vdash a : A}{\Gamma \vdash Fa : (\Pi_{x:A}.B)a}$$

[31] solved the problem by re-incorporating Frege and Russell's notions of low level functions (which was lost in Church's notion of function).

The same problem and solution can be repeated in our $\flat$-cube.

Adding type instantiation to the typing rules of the $\flat$-cube

If we change (app$\flat$) by (new app$\flat$) in the $\flat$-cube we lose subject reduction.

$$(\text{app}\flat)\quad \frac{\Gamma \vdash_\flat F : (\Pi_{x:A}.B) \qquad \Gamma \vdash_\flat a : A}{\Gamma \vdash_\flat Fa : B[x := a]}$$

$$(\text{app}\flat\flat)\quad \frac{\Gamma \vdash_\flat F : (\flat_{x:A}.B) \qquad \Gamma \vdash_\flat a : A}{\Gamma \vdash_\flat Fa : (\flat_{x:A}.B)a}$$

Failure of correctness of types and subject reduction

- **Correctness of types no longer holds.** With (appl$\flat\flat$) one can have $\Gamma \vdash A : B$ without $B \equiv \Box$ or $\exists S \,.\, \Gamma \vdash B : S$.

- For example, $z : *, x : z \;\vdash\; (\flat_{y:z}.y)x \;:\; (\flat_{y:z}.z)x$ yet $(\flat_{y:z}.z)x \not\equiv \Box$ and $\forall s \,.\, z : *, x : z \;\not\vdash\; (\flat_{y:z}.z)x : s$.

- **Subject Reduction no longer holds.** That is, with (appl$\flat$): $\Gamma \vdash A : B$ and $A \twoheadrightarrow A'$ may not imply $\Gamma \vdash A' : B$.

- For example, $z : *, x : z \;\vdash\; (\flat_{y:z}.y)x : (\flat_{y:z}.z)x$ and $(\flat_{y:z}.y)x \to_\flat x$, but one can't show $z : *, x : z \;\vdash\; x : (\flat_{y:z}.z)x$.

Solving the problem

Keep all the typing rules of the $\flat$-cube the same except: replace (conv) by (new-conv), (appl$\flat$) by (appl$\flat\flat$) and add three new rules as follows:

(start-def) $$\frac{\Gamma \vdash A : s \quad \Gamma \vdash B : A}{\Gamma, x = B{:}A \vdash x : A} \qquad x \notin \mathrm{DOM}(\Gamma)$$

(weak-def) $$\frac{\Gamma \vdash A : B \quad \Gamma \vdash C : s \quad \Gamma \vdash D : C}{\Gamma, x = D{:}C \vdash A : B} \qquad x \notin \mathrm{DOM}(\Gamma)$$

(def) $$\frac{\Gamma, x = B{:}A \vdash C : D}{\Gamma \vdash (\flat x{:}A.C)B : D[x := B]}$$

(new-conv) $$\frac{\Gamma \vdash A : B \quad \Gamma \vdash B' : s \quad \Gamma \vdash B =_{def} B'}{\Gamma \vdash A : B'}$$

(appl$\flat\flat$) $$\frac{\Gamma \vdash F : \flat_{x:A}.B \quad \Gamma \vdash a : A}{\Gamma \vdash Fa : (\flat_{x:A}.B)a}$$

In the conversion rule, $\Gamma \vdash B =_{def} B'$ is defined as:

- If $B =_\flat B'$ then $\Gamma \vdash B =_{def} B'$
- If $x = D : C \in \Gamma$ and B' arises from B by substituting one particular free occurrence of x in B by D then $\Gamma \vdash B =_{def} B'$.
- Our 3 new rules and the definition of $\Gamma \vdash B =_{def} B'$ are trying to re-incorporate low-level aspects of functions that are not present in Church's λ-calculus.
- In fact, our new framework is closer to Frege's abstraction principle and the principles $*9{\cdot}14$ and $*9{\cdot}15$ of [49].

Correctness of types holds.

- We demonstrate this with the earlier example.
- Recall that we have $z : *, x : z \vdash (\flat_{y:z}.y)x : (\flat_{y:z}.z)x$ and want that for some s, $z : *, x : z \vdash (\flat_{y:z}.z)x : s$.
- Here is how the latter formula now holds:

$$
\begin{array}{ll}
z : *, x : z \vdash z : * & \text{(start and weakening)} \\
z : *, x : z.y : z\rangle x \vdash z : * & \text{(weakening)} \\
z : *, x : z \vdash (\flat_{y:z}.z)x : *[y := x] \equiv * & \text{(def rule)}
\end{array}
$$

Subject Reduction holds.

- We demonstrate this with the earlier example.
- Recall that we have $z : *, x : z \vdash (\flat_{y:z}.y)x : (\flat_{y:z}.z)x$ and $(\lambda_{y:z}.y)x \rightarrow_\beta x$ and we need to show that $z : *, x : z \vdash x : (\flat_{y:z}.z)x$.
- Here is how the latter formula now holds:

$a.$	$z : *, x : z \vdash x : z$	(start and weakening)
$b.$	$z : *, x : z \vdash (\flat_{y:z}.z)x : *$	(from 1 above)
	$z : *, x : z \vdash x : (\flat_{y:z}.z)x$	(conversion, a, b, and $z =_\beta (\flat_{y:z}.z)x$)
